

Exploring the Determinants of Company's Dividend Payout Policy in Vietnamese Stock Market

Cheng-Wen Lee¹, Hui-Hsin Hsu^{2*}, San-Jung Peng³, and Tuyet Nhu Huynh Nguyen⁴

Abstract

Vietnamese stock market exists in one of the most dynamic emerging countries in East Asia. As expected, stock market has worked well to push up Vietnamese economy. Due to the information asymmetry, investors often rely on the dividend payment as an indicator to predict the company's future prospects. Dividend policy is a significant concern of both financial managers in shareholding firms and outside investors. Dividend payout policy is always considered as one of the most important decisions in financial management. The aim of dividend policy is to allocate retained earnings for reinvestment and dividends for shareholders. Specially, in Vietnam, the securities are still fresh to investors and people alike. This research investigates the determinants of dividend policy in Ho Chi Minh Stock Exchange in Vietnam, an emerging stock market that was officially established in July, 2000. This research evaluates whether the factors affect company's dividend policy such as profitability, firm size, financial leverage and growth rate, etc. This research data is collected from enterprises listed on the Vietnam stock market in the period of 2014-2018 with 756 observations, and is analyzed by Ordinary Least Square model and Fixed Effect model and Random Effect model. Based on the Hausman Test result, Fixed Effect model is the most consistent model of examining the factors affecting the dividend payout policy.

Keywords: dividend policy, Vietnamese stock market, dividend payout ratio, ordinary least square, fixed effect model.

1. Introduction

Dividend payment is the distribution of net profit after tax to a company's shareholders after keeping a specific amount of earnings to reinvest in the business. Dividend policy is one of the most important decision in financial management of company. Companies must makes a choice as to what part of the profit to retain and to spend on investment, development and how much of it to transfer to shareholders. Decision on the distribution rate between retained earnings and profit using to pay for dividends to shareholders expressed through the dividend policy. Retaining part of the company's profit and its uses as a source of financing of development projects contributes to the increase in the value of such an entity, and thus leads to an increase in the value of its share (Sierpinska and Jachna, 2007, p.311). In order to make a reasonable dividend payment decision, enterprises need to consider many factors.

The stock market has appeared in the world for centuries, but it was only established in Vietnam market more than 20 years ago. It started with the establishment of the State Securities Commission – the regulator over the securities market in 1997. Viet Nam stock market includes Ho Chi Minh City Stock Exchange (HSX) – Viet Nam's largest stock exchange and Ha Noi Stock Exchange (HNX). In the initial stage of the stock market, with the establishment of Ho Chi Minh Stock Exchange on 20 July in 2000, there was only 2 listed company with total capitalization of 986 billion VND (amounting to 0.28%/GDP in 2000). If Ho Chi Minh City Securities Trading Center is a place to list securities transactions of large companies, Hanoi Securities Trading Center is a place where listing of small and medium enterprises is concentrated.

Table 1: Counts of listed firms in Vietnamese stock market from 2005 - 2018

Year	2005	2006	2007	2009	2011	2013	2015	2017	2018
HSX	23	81	107	175	275	284	307	344	373
HNX	8	86	116	236	356	369	377	384	376

Source: collected by author from data of Ho Chi Minh Stock Exchange and Ha Noi Stock Exchange.

For the last 20 years, Vietnam's stock market has experienced a lot of changes, but it is also growing more and more strongly, through many different periods. The Vietnam stock market has grown significantly, at the beginning of the market in 2000 there were only 2 listed companies (DNNY) but on August 15, 2018, HOSE had 410 listed securities codes, including 361 stocks and 45 bonds. Vietnamese stock market started to develop rapidly in 2006. In the last 5 years , the market capitalization has increased rapidly with the growth rate of over 25%. The number of listed companies in 2006

increase from 31 to 167, over 5 times higher than in 2005 (table 1). If the market capitalization in 2013 was only VND 842 trillion, by August 15, 2018, this figure had reached VND 3.07 million, equivalent to 61.27% of GDP. The period from 2000 to 2005 marked the beginning of the stock market, or it was considered a toddler period. During this period, there are about 30 corporations listed in both stock exchanges, market capitalization reached just under 1% of GDP, almost no change at all. However, Vietnamese stock market started to develop rapidly in 2006.

Figure 1: Performance of VN-INDEX and HNX-INDEX from 2010-2018

Source: Compiled by author with data from Ho Chi Minh City Stock Exchange and Ha Noi Stock Exchange

Through the period from 2006, when the Law on Securities was enacted and officially took effect from the beginning of 2007, it gradually improved the inadequacies, conflicts with other legal documents, helped the market. Vietnam stock market has the ability to integrate more with international and regional capital markets. Vietnam's stock market becomes more transparent and safe, increasing the ability to manage and supervise state management agencies. In terms of market size, 2006 marked a strong leap when reaching 22.7% of GDP, the figure even continued to increase strongly to over 43% in 2007. Of course "up there must be down", due to the influence of the financial market and the economy of the country and the world, 2008 is a year of "sad market" with market capitalization falling sharply, down to 18% of GDP. Through 2009, the market began to recover slightly with a market capitalization of 37.71% of GDP. Accompanying this recovery is the significant increase of listed companies in the market.

Table 2: Vietnam tax policy on dividends and capital gains from 2013 - 2018

	1st sub-period		2nd sub-period		3rd sub-period	
	Dividends	Capital gains	Dividends	Capital gains	Dividends	Capital gains
Individual investors	0%	0%	0% and 5%	0% ^a and 20% or 0.1% of selling price ^b	0%	10% or 0.05% of selling price
Vietnamese institutional investors	0%	28%	0%	25%	0%	25%
Foreign institutional investors	0%	0.1% of selling price	0%	0.1% of selling price	0%	0.1% of selling price

Source: Circular No. 100/2004/TT-BTC, Law No. 09/2003/QH11, Law No. 14/2008/QH12, Law No. 04/2013/QH12, Circular No. 134/2014/TT-BTC, Decree No. 101/2018/ND-CP and Circular 160/2015/TT-BTC.

Note: 1st sub-period is from January 2013 to December 2015; 2nd sub-period is from January 2016 to July 2018; 3rd sub-period is from August 2018 to December 2018; a From to January 2016 to December 2016; b From January 2017 to July 2018.

From 2013 to 2018, there are three sub-periods of tax policy on dividends and capital gains in Vietnam. From January 2013 to December 2018, individual investors' dividends and capital gains were exempt from income tax while Vietnamese institutional investors' capital gains were charged at the rate of 28% and foreign institutional investors' capital gains were taxed at 1% of selling price. In the second period, dividends and capital gains of individual investors were exempt from income tax from to January 2016 to December 2016; then, they were charged 5 % and 20% or 0.1% of selling price respectively from January 2017 to July 2018. In addition, the tax rate for Vietnamese institutional investors' capital gains was reduced to 25%. In the third sub-period, Vietnamese government reduced tax rates for individual investors' dividends and capital gains to 0% and by half respectively as a means to support individual investors in economic recession (Table 2).

And so far, market capitalization has skyrocketed to more than 82% of GDP, reflecting a boom in the stock market. The year 2017 has marked strong economic growth in Vietnam's market, with GDP (Gross Domestic Product) going up about 6-7% and it keeps increasing. As a result, Vietnam recently has become Asia's fastest

growing stock market with 100% growth in 5 years. The latest report compiled by the State Securities Commission shows that by the end of January 2019, there were 755 stocks and fund certificates listed across the market and 804 stocks registered on the UPCOM with total listing value of more than VND1,235 trillion, up 26 percent compared to the end of 2017. In addition, market capitalization rose 12.7 percent compared to 2017, accounting for 71.6 percent of the country's gross domestic product, exceeding the government's plan for 2020. Stock market is now becoming the important capital mobilization channel for Vietnam economy, become remarkable capital mobilization channel to push up national economic and maintain a high development speed.

The stock market has brought great value and positive impacts to the Vietnamese economy. It is also an important capital mobilization channel to promote the development of enterprises and investors. However, the stock market is still a risky investment channel. The Vietnamese market will have to continue to maintain and improve the criteria set out within a minimum review period of one year. The recognition from FTSE Russell would help change the status of the national financial market, promising positive impact on its ability to attract foreign investment, as well as improving market liquidity, the quality of listed companies and motivation to improve the legal framework further.

Especially, Viet Nam is a new stock market, due to the information asymmetry, investors often rely on the dividend payment as a viewpoint to predict the company's future prospects. Dividend policy is a significant concern of both financial managers in shareholding firms and outside investors. Specially, in Viet Nam, securities are still fresh to investors and people alike; and this can cause confusion when choosing whether to make buy, hold or sell decisions about stocks. Thus, findings which show how Vietnamese firms' features and corporate governance affect dividend policy will be of real importance to external investors interested in stock market investment in Vietnam. The role and the application of dividend policy are supported by different theories such as signaling theory, trade-off theory, agency theory, transaction cost theory and pecking order theory. Until now, several researchers have continued to prove and developed these theories in order to determine the factors which influence the dividend policy of a joint-stock enterprise.

Generally, there are two main groups of factors comprising firm's characteristics and corporate governance. Firm's characteristics include several factors such as profitability (Lintner, 1956; Fama and French, 2002), firm size (Farinha, 2003; Bebczuk, 2005), debt level (Chang and Rhee, 1990; Belden et al., 2005), liquidity (Ho, 2003; Myers and Bacon, 2004), asset structure (Myers, 1984; Koch and Shenoy, 1999), industry type (Baker and Powell, 2000; Naceur et al., 2006), growth opportunities

(Kowalewski et al., 2008; Al-Najjar and Hussainey, 2009) and business risk (Aivazain et al., 2003; Li and Zhao, 2008). Corporate governance consists of management ownership (Jensen et al., 1992; Short et al., 2002), ownership concentration (Khan, 2006), board of directors (Bathala and Rao, 1995) and audit quality (Deshmukh, 2005). It is found that factors impacting dividend policy are still the subject of debate. The below fact provides the reason for this research's examination of the determinants of dividend policy in Viet Nam, a developing country with the emerging stock market in Asia.

Firstly, international study published made for the case of Viet Nam is not yet available. There were several researchers who investigated dividend policy in developed countries like this USA (Chang and Rhee, 1990)... even the research regarding this topic in other developing countries are quite common, such as Ramli(2010) in Malaysia, but no researchers have been done in Vietnam about the determinants of its dividend policy. Also, there are differences existing in dividend payment policy between countries. If have been a number of studies on dividend policy of listed companies in stock market, these research has only provided dividend policy analyzes and factors affecting dividend policy. This study, on the one hand, provides a more accurate assessment of the factors that influence the dividend policy of listed companies in stock market over a long period of time with the dependent variable measured (Dividend payout ratio - Dividend Per share ratio). Finally, this study will be based on those assessments to suggest Vietnamese companies to adopt appropriate dividend policy. Secondly, dividend policy is the most concern topic with financial researchers and I think Viet Nam stock market is a attractive market for investors. So this research will help companies how to built their dividend policy to attract foreign investment and also help investors how to invest in the Viet Nam Stock Market, give the right eye. Thirdly, the study is expected to bring out a clear and comprehensive approach of portfolio selection.

2. Literature Review

2.1 School of thought

Dividend policy is always consider as one of the most important policy that a company uses to structure its dividend payout to shareholders and that is also what investors interested when they are investing in a company. The dividend payment may affect directly the interest of shareholders and the retain for future development of a corporate company. Some researchers suggest that dividend policy may be irrelevant in theory, because investors can sell a portion of their shares or portfolio if they need funds.

Dividend policy has been the subject of considerable debate since Miller and Modigliani (1961) dividend policy is irrelevant. It does not affect to value of company,

not influence on a company's share price. They argued that the cost of capital depends on the company's ability to generate income and risks associated with its business, rather than the dividend policy. The value of company depends on investment decision.

On the contrary, according to the creators of the tax preference theory (Brennan, 1970; Elton and Gruber, 1970; Litzenberger and Ramaswamy, 1979; Litzenberger and Ramaswamy, 1982; Kalay, 1982; John and Williams, 1985; Poterba and Summers, 1984; Miller and Rock, 1985; Ambarish, 1987) suggest that high dividend pay out reduces the value of the company, dividends are subject to higher tax cut than capital gains.

On the other hand, Gordon's theory of "The bird in hand", he argued that the cost of capital increases when the payment of dividends is limited. An increase in dividend payments leads to an increase in the value of the company. Gordon indicated that change in the company's dividend payout ratio would change investors risk level when investing in stocks of company. A high dividend payment corporate would reduce the risk or limit uncertainty about future income flows for shareholders, thus attracting more investors, and vice versa. A high-dividend are paid out by companied to satisfy shareholders' desire for current income. This theory can be understood by intuition, since individuals naturally tend avoid risk in the future and current dividend provide them a sense of security. This means that behavior of the shareholders would affect dividend policy of the company.

Free cash flow theory: One implication from Jensen's free cash flow theory is that firms with high levels of free cash flow are more likely to initiate takeovers and investments that are value-decreasing. Managers of firms with excess cash flow will be pressured to pay the excess out to investors as opposed to reinvesting the cash in less profitable opportunities. As payouts to shareholders increase, the stock price will be pushed up. If the firm retains the excess cash the decreasing marginal utility of the investments available will cause the returns and the stock price to deteriorate. The deterioration of the stock price in a business with free cash flow makes the business an attractive takeover target. This is because there are more profitable uses of the cash (generated by the firm) outside the firm; this cash should be returned to the stockholders to be invested in those more profitable opportunities.

2.2 Research in Vietnam

Alphonse and Tran (2014) conducted a study investigated dividend policy in Vietnamese stock market with Heckman's two-step regression approach which fixes the selection bias caused by censored research data. Research findings show that in the first step, likelihood of dividend payment is positively affected by profitability, firm size and earned/contributed capital mix and state control while it is negatively related to investment opportunities, stock liquidity and insider ownership. In the second step, investment opportunities and insider retention have a negative impact on dividend

yields while leverage has negative and positive impacts on payout ratio and dividend yield respectively. Contrary to free cash flow hypothesis, free cash flows to total assets ratio is negatively related to payout ratio.

Dang and Nguyen (2018) explored the factors affecting company's dividend policy such as profitability, firm size, financial leverage and growth rate. The authors have identified two factors that have a positive and significant effect: (i) return on total assets and (ii) firm size. At the same time, research results also show a negative impact of enterprise's revenue growth rate on the dividend payment ratio. In addition, financial leverage has no impact on company's dividend policy.

Nguyen and Bui (2018) examined the determinants of the dividend policy of non-financial companies listed on the Vietnam Stock Market for the period 2008-2015 with the binary dependent variable. This research shows that profitability, the level of money holdings, the liquidity of stocks and the life cycle of companies play an important role in dividends policy. In addition, growth opportunities and financial leverage also have an effect on dividend payments decision. Meanwhile, the other two factors namely the firm size and the risk does not affect the decision.

With these contradictory research results, it is needed to have an explicitly research based on empirical results. In Vietnam, although there have been a number of studies on dividend policy of listed companies in stock market, these research has only provided dividend policy analyzes and factors affecting dividend policy. This study, on the one hand, provides a more accurate assessment of the factors that influence the dividend policy of listed companies in stock market over a long period of time with the dependent variable measured (Dividend payout ratio - Dividend Per share ratio). Finally, this study will be based on those assessments to suggest Vietnamese companies to adopt appropriate dividend policy.

2.3 Hypotheses development

Relationship between Profitability and Dividend payout ratio

The financial literature documents that a firm's profitability is a significant and positive explanatory variable of dividend policy (Jensen,1992; Han, 1999; Fama and French, 2000). This factor directly affects the company's dividends payment ability (Lintner, 1956). Companies paying high dividend have high profit (Baker and Powell, 2000; Nizar Al-Malkawi, 2007). In Vietnam, some studies show that return on total assets (ROA) are positively affect to the company's dividend policy (Dinh and Nguyen, 2014). Earning Per Share (EPS) is one of the factors that have a positive influence on the dividend decision (Nguyen, 2014).

$$\text{Profitability (PROF)} = \frac{\text{net income}}{\text{Average total assets}}$$

H₁: Profitability has positive relationship with dividend policy.

Relationship between Firm size and Dividend payout ratio

Large companies have an easy access to capital market and a low cost capital mobilization because credit institutions believe their repayment capabilities, so it is not necessary to use internal funds. Thus, firm size has an inversely relation with the level of internal fund dependence or large company can pay higher dividends (Al-Yahyaee, Pham and Walter, 2006; Al-Shubiri, 2011). According to the creators - Eddy and Seifert (1988), Jensen (1992), Redding (1997), Fama and French (2000), large firms distribute a higher amount of their net profits as cash dividends, than do small firms.

Other studies related the positive association between dividends and firm size to transaction costs. For example, Holder (1998) revealed that larger firms have better access to capital markets and find it easier to raise funds at lower costs, allowing them to pay higher dividends to shareholders. This demonstrates a positive association between dividend payouts and firm size. The positive relationship between dividend payout policy and firm size is also supported by a growing number of other studies (, Eddy and Seifert, 1988; Jensen, 1992; Redding, 1997; Holder, 1998; Fama and French, 2000; Manos, 2002; Mollah, 2002; Travlos, 2002; Malkawi, 2007).

$$\text{Firm Size (SIZE)} = \text{Ln}(\text{revenue})$$

H₂: Firm Size has positive relationship with dividend policy

Relationship between Financial Leverage and Dividend payout ratio

A growing number of studies have found that the level of financial leverage negatively affects dividend policy (Jensen, 1992; Agrawal and Jayaraman, 1994; Crutchley and Hansen, 1989; Faccio, 2001; Gugler and Yurtoglu, 2003; Al-Malkawi, 2005). Their studies inferred that highly levered firms look forward to maintaining their internal cash flow to fulfil duties, instead of distributing available cash to shareholders and protect their creditors. However, Mollah, (2001) examined an emerging market and found a direct relationship between financial leverage and debt-burden level that increases transaction costs. Thus, firms with high leverage ratios have high transaction costs, and are in a weak position to pay higher dividends to avoid the cost of external financing. To analyze the extent to which debt can affect dividend payouts, this study employed the financial leverage ratio, or ratio of liabilities (total short-term and long term debt) to total shareholders' equity.

The financial leverage shows the total debts over the total liabilities and owners' equity. The higher debts the firms use, the more control by creditors and the more financial risk they may face. Therefore, if the firms have higher financial leverage, the dividend ratio may be lower. This was researched by a lot of economists such as Rezeff, 1982; Myers, 1984; Jensen, 1986; He, 2009; Mehta, 2012 and so on. The firms

must spend money and assets to creditor before paying dividend to shareholders. Besides, firms keeping the high debts ratio may reduce the dividend ratio if they do not want to face to high costs when increasing funds outside. The financial leverage has been measured by the total liabilities over the equity.

$$\text{Financial leverage (LEV)} = \text{Debt/Total asset}$$

H₃: Dividend payout is negatively associated with the financial leverage.

Relationship between Liquidity and Dividend payout ratio

Liquidity ratios are an important class of financial metrics used to determine a debtor's ability to pay off current debt obligations without raising external capital. Liquidity is the extent at which a firm can pay short-term liabilities based on its liquid assets (Atrill and McLaney, 2002). Ho (2003) found that the more liquid firms in Japan have higher dividend payouts. Mehar (2002), however, suggested there is an inverse relationship between liquidity position and dividend payments from his study of companies on the Karachi Stock Exchange in Pakistan as firms with positive working capital will lower dividends. Myers and Bacon (2004) highlighted that corporations are likely to lessen dividends to spread liquidity. However, a few years later, Al-Najjar and Hussainey (2009) proved that paying lower or higher dividends does not depend on a good or bad liquidity position. Since there is still a debate about this association, this study will test whether the dividend policy of companies in Vietnam is impacted by liquidity.

$$\text{Liquidity(CR)} = \text{Total cash/current debt}$$

H₄: Dividend payout is positively associated with the firm liquidity

Relationship between Free cash flow and Dividend payout ratio

Based on the argument of agency problem, Rozeff (1982) develops free cash flow hypothesis stating that dividend payment is a device to mitigate excessive funds which managers can use to invest in negative net present value projects. Holder (1998) initially employ free cash flow to test agency theory with the sample of 477 firms listed in US stock market between 1983 and 1990. Their research findings show firms with higher free cash flows pay lower levels of dividends. Therefore, this study hypothesizes that there is a positive relationship between free cash flow and dividend payout ratio.

$$\text{Free cash flow(FCF)} = (\text{Operating income} + \text{depreciation} - \text{taxes} - \text{interest expenses} - \text{preferred dividends} - \text{ordinary dividends})/\text{total assets}$$

H₅: Free cash flow is positively related to dividend payout ratio

Relationship between Insider ownership and Dividend payout ratio

In addition, Rozeff (1982) posit that insider ownership is a measure of agency costs. Lower insider ownership indicates higher agency costs; therefore, outsiders who hold larger percentage of shares will demand higher dividends to reduce agency costs.

Holder (1998); Rozeff (1982) find empirical evidence supporting the negative relationship between the percentage of insider ownership and dividend payments.

Insider ownership(INS): proportion of shares held by insiders.

H₆: Insider ownership is negatively related to dividend payout ratio

Relationship between Earnings per Share and Dividend payout ratio

Dividend payout ratio on the earnings per share: Chay and Sub (2009) suggest that this factor has a positive relationship with the dividend payment ratio as firms with a strong cash flow are capable of paying higher dividends as compared to firms with weaker cash flows.

$$\text{Earnings per Share} = \frac{\text{Net Income} - \text{Preferred Dividends}}{\text{Weighted Average Common Shares Outstanding}}$$

H₇: Earnings per share is positively related to dividend payout ratio

Dependent variable: Dividend payout ratio

The dividend payout ratio (DIV) is the proportion of total profit distributed in the form of dividends, the amount that is not pay to shareholder is called retained profit. It is retained by the company to pay off debt. Dividend payout ratio is the number of dividends paid to shareholders on the total net income of a company. Amount of money not to pay dividends to shareholders is retained by the company for investment growth. The money held by the company is called retained earnings. The net income shown in the formula can be found on the company's income statement. This formula is used by some investors when considering whether to invest in a profitable company that pays dividends every year or a profitable company that has high potential for growth. In other words, this formula looks at a stable income with reinvestment for potential future earnings, assuming that the company has an annual net income.

$$\text{Dividend payout ratio} = \frac{\text{dividends}}{\text{net income}}$$

3. Methodology and Data

3.1 Methodology

In this study, I will focus on identify the factors affect dividend policy of listed companies possible appearance in the Vietnam Stock Market. In this research, Eviews 8 is used to analyze the collected data. This study is explanatory research with a quantitative approach. The data used in this research was secondary data. Secondary data is data that is published or utilized by the other organization, not by the user. The data were gathered from the official website of Ho Chi Minh Stock Exchange (www.hsx.vn) and company annual report. For additional information, the researcher also takes information which has already existed, like articles, journals, text books, and etc.

According to the hypotheses development, there are 7 variables to be tested including: profitability, firm size, financial leverage, liquidity, free cash flow, insider ownership and earnings per share. And the dependent variable is dividend payout ratio. The relationship among explanatory variables will be tested using a Ordinary Least Squares, Fixed Effect Model and Random Effect Model regression model to determine the significance, sign and magnitude of the effect of each variable on dividend payout ratio. The objective is to detect near multicollinearity using the correlation matrix. Another test that the paper will perform is the test to detect the presence of heteroscedasticity or the presence of inconstant variance. Bias standard errors lead to biased inference of the data, making the estimated results of hypothesis tests possibly inaccurate.

The paper will then run two classes of estimator approaches to determine which model fits the panel data. First, the FE model assumes correlation between error term and variables. Second, the RE model on the other hand assumes that the variations across the entities are random and uncorrelated with the explanatory variables. This model also considers the inclusion of the cross section and period. This study will perform the Hausman test on the panel data set to examine the suitability of either the FE model or the RE model. The following regression model was used to test the determinants of dividend payout of the listed companies in Vietnam stock market:

$$DPR_{it} = \beta_0 + \beta_1 PROF_{it} + \beta_2 SIZE_{it} - \beta_3 LEV_{it} + \beta_4 CR_{it} + \beta_5 FCF_{it} - \beta_6 INS_{it} - \beta_7 EPS_{it} + \varepsilon_{i,t};$$

This research is used by Ordinary Least Square and Fixed Effect Model and Random Effect Model. In order to choosing model consistent with the hypotheses and it can explain relationship between variables, author used Hausman test and Likelihood ratio.

3.2 Determinants of dividend payout

This research strongly focuses on investigating the factors to affect possible appearance in the Vietnamese stock market. As the dividend payout ratio is considered as a sign of an investors' return and of a company's future prospect, it is chosen as the dependent variable to explain the factor effect of dividend policy.

For specific, the variables using in this research are defined as the table:

Table 3: Definitions of exploratory variables

Variables	Definition	Expected sign of variables
Profitability	Net income divided by total assets	+
Firm size	Ln(revenue)	+
Financial leverage	Total Liabilities/ Total Assets	-
Liquidity	Current ratio	+
Free cash flow	(Operating income + depreciation - taxes - interest expenses - preferred dividends - ordinary dividends)/total assets	+
Insider ownership	Proportion of shares held by insiders	-
Earnings per Share	(Net income – Preferred Dividends) / Weighted Average Common Shares Outstanding	+

Source: Collected by author.

3.3 Data collection

In this study, I will focus on identify the factors affect dividend policy of listed companies possible appearance in the Vietnam Stock Market. The data are collected from listed companies on Ho Chi Minh City stock market for 5 years (2014-2018) with 756 observations (unbalanced data) and the regression model is based on panel data. This research collects financial statements, which include balance sheet and income statement of listed companies in the Ho Chi Minh Stock Exchange (<http://hsx.vn>). All financial and accounting data are gathered from the databank of Ho Chi Minh Stock Exchange (HOSE) as well as the source supplied of VnDirect website (<http://vndirect.com.vn>). The data are gathered from balance sheet, financial statement... of listed company in Ho Chi Minh Stock Exchange from the data 2014-2018.

4. Empirical Results

4.1 Descriptive Statistic

This research used the statistical program EViews version 8.0 to run the Testing from sample observation. The results are as following:

Table 4: Descriptive statistic of variables – HCM stock exchange(HOSE)

Variable	Mean	Median	Std. Dev	Min	Max	Obs
PROF	0.0674	0.05	0.0907	-0.5	0.9549	754

Note:1. The dependent variable DIV denotes Dividend Payout Ratio. 2.The controlling variable PROF denotes return on asset in the year, SIZE denotes firm size (natural log of total asset); LEV denotes long-term debt / total asset ratio; CR mean current ratio; FCF denotes free cash flow/ total asset; INS denotes insider ownership; EPS denotes the earning/per share ratio.

Table 2 shows the descriptive statistics for listed firms in the Ho Chi Minh Stock Exchange (HOSE); it is clear that on average, the average dividend payout ratio of the 154 listed companies during 2014 and 2018 is 39.68% with a standard deviation of 31.02%. This means, on average, the listed companies on the Ho Chi Minh stock market spent 39.68% of their net profit to pay dividends. This table illustrates that a fluctuation gap of the dividend payout ratio of listed companies in the HOSE is quite large with a maximum value of 247% and a minimum value of 0%. In addition, this table describes the average value, standard deviation and fluctuation gap of 7 independent variables. Average Return On Assets (ROA) - PROF is 6.80%. The logarithm of total revenue (SIZE) is 12.85%, average Financial Leverage (LEV) is 14.03% and average free cash flow (FCF) is 5.67%. Businesses usually pay cash dividends from 1-2 times a year, but in particular there are companies paying cash dividends 5 times a year. Average Return On Assets (ROA) is 6.80%. Examining the Finance Leverage, it may recognize that the ratio is not too high, on average at 14.03% only, this means the listed companies are

willing to raise the fund in the equity market, instead of borrowing money from banks or other financial institutions.

4.2 Correlation analysis

Table 5: Correlation coefficients matrix – HCM stock exchange (HOSE)

	DIV	PROF	SIZE	LEV	CR	FCF	INS	EPS
DIV	1							
PROF	0.109351*	1

	0.047589							

Source: data extracted from financial statements and calculated from EViews 8.0

Note: 1. The dependent variable DIV denotes Dividend Payout Ratio. 2. The controlling variable PROF denotes return on asset in the year, SIZE denotes firm size (natural log of total asset); LEV denotes long-term debt / total asset ratio; CR mean current ratio; FCF denotes free cash flow/ total asset; INS denotes insider ownership; EPS denotes the earning/per share ratio.

From Table 3, for the Ho Chi Minh sample, describes the correlation coefficients among the variables of listed companies in the HOSE. Most of the independent variables have a low correlation with the others, but represent quite high correlations between FCF and PROF, LEV and SIZE, CR and PROF (0.11618; 0.11016; 0.129091 respectively) that may cause the multicollinearity in the model. However, this sign has an insignificant effect on the regression model in general. Therefore, most of the independent variables have no strong correlation and show a good sign to test the model in the next section. All of the key explaining for the hypothesis development (PROF, SIZE, LEV, FCF, INS) are significant at 10% level and most of them positively related to the dividend payout ratio. The dependent variable DIV have a correlation relationship with PROF, SIZE, LEV, FCF, INS at the 0.01 level and 0.05 level.

1. Relationship between DIV and profitability (PROF)

The dividend pay out ratio has a significant correlation with profit, the value is 0.109 , that mean is a positive correlation between two variables but it is weak and significant. This is explained in that when ROA increases, DPR will increases.

According to the research assumption, firms with high and stable profitability may have a strong cash flow to pay dividends.

2. Relationship between DIV and firm size (SIZE)

Table 3 shows the value correlation between dividend pay out ratio and firm size is -0.086347. This means they have a negative relationship which is actually in contrast with paper's hypothesis that firm size is positively related to dividend payout policy.

3. Relationship between DIV and finance leverage (LEV)

The dividend payout ratio of the company in Ho Chi Minh Stock Exchange has a negative relationship with finance leverage, the value is -0.108237 mean is a negative correlation between two variable. This result is consistent with this thesis hypothesis. The higher debts the firms use, the more control by creditors and the more financial risk they may face. Leverage can also refer to the amount of debt a firm uses to finance assets. If a firm is described as highly leveraged, the firm has more debt than equity. Therefore, if the firms have higher financial leverage, the dividend ratio may be lower.

4. Relationship between DIV and free cash flow (FCF)

The dividend payout ratio has positive relationship and significant with free cash flow variable, the value is 0.0855. It means dividend pay out will increase when free cash flow of the company increased.

5. Relationship between DIV and insider ownership (INS)

Table 3 show that dividend payout ratio and insider ownership have a negative relationship with the value is -0.007046 at significant 0.01 level. This result is consistent with the paper's hypothesis. The firm have a larger number insider shareholder which will pay less dividend.

6. Relationship between DIV and firm liquidity (CR)

The correlation relationship value shown at the table 3 indicate that there are positive relationship and significant 0.01 level. The correlation coefficients matrix among variables is used to analyze and examine the probability of multicollinearity occurrence. Based on the data on table 4, the likelihood of multicollinearity in the regression model is small because most of the correlations among variables are relatively small. None of the cases have the absolute value exceeds 0.6

Table 6: Durbin Watson test results for Autocorrelation

Model Summary				
Model	R square	Adj R Square	Std. Error	Durbin Watson
Fem	0.0399	0.0309	0.305	1.415
Independent variable: PROF, SIZE, LEV, CR, FCF, INS, EPS				
Dependent variable: DIV				

Durbin Watson test (2002) is used for checking the autocorrelation for unbalanced panel data. The Durbin-Watson test statistic tests the null hypothesis that the residuals from an ordinary least-squares regression are not autocorrelated against the alternative that the residuals follow an AR1 process. 1. The Durbin Watson test statistic value is 1.415 that mean there is no autocorrelation detected in this sample. The results of this study is more exactly.

4.3 Empirical Results

According to Arellano(1987), for the term of fixed T , it is a common practice to use the White period estimator in favor of the White cross section or the White diagonal estimator. Thus, in this research , the coefficient covariance method has been chosen as the White Period. Using the Likelihood Model for cross-section F-test , the Prob is lower than 0.01, it proofs that the Panel data effects option should be used instead of Pooled OLS.

Table 7: Results based on Ordinary Least Squares, Fixed Effect Model, Random Effect Model (2014-2018)

	OLS	FEM	REM	Obs (N)

Table 9: Result of the Hausman test

Test summary	Chi-Sq Statistic	Chi-Sq .d. f	Prob
Cross section random	12.253394	7	0.0925

The Hausman Test is used for choosing between the Fixed Effect Model and Random Effect Model with hypothesis:

H0: Random Effect Model is appropriate.

H1: Fixed Effect Model is appropriate.

This research shows 3 models: Pooled OLS, FEM and REM, in which the REM is not appropriate to explain the changes of DPR. Because based on the result of the Hausman test with the p value is 0.0925 and Chi Square > Prob. So the hypotheses H0 is rejected. Therefore, the Likelihood test is conducted to choose between Pooled OLS and FEM. The null hypothesis is “the Pooled OLS is appropriate”. The P-value, which is approximately 0%, proves that the null hypothesis is rejected and the Fixed Effect Model is chosen. The result of FEM points out that there 5 factors including the financial leverage, return on asset and firm size, free cash flow and insider ownership among 7 factors having a significant relationship with the dividend payout ratio of listed companies in the HOSE. Specifically, as can be seen from the result that the coefficient of the EPS variable is approximately 0 (-0.0025), this factor is not statistically significant with the DPR. And the value of the liquidity is 0.0022 is also approximately 0 which shows that this liquidity variable is not statistically significant with dividend payout ratio.

In dividend policy studies, depending on the availability of data, only a few basic factors can be considered in many different factors. So R-square result is low that is a common result, as research Gill(2010); with the R -square value is 0.152 and 0.088. And the research Bistрова and Lace (2012) with the R-square value is 0.0589. The low R square value suggests that there are other factors that affect the dividend policy of Vietnamese companies have not been put in the model yet. We have to consider many

factor may be tax, business risks, turnover ratio...Factors which do not have official data in Vietnam yet or are factors that do not change over time such as industry or owner.

Table 5 shows the determinants of dividend payout policy to test for the precision of Hypothesis. The larger firms with better accounting performance on Asset are likely to pay lower dividend. With the negative coefficient in financial leverage variable, the small leverage companies seems to pay higher dividend. Analyzing the hypothesis testing for the determinants of dividend payout ratio, the results are mostly consistent with research's hypothesis. As of my hypotheses assumption, companies with high profitability, high concentrated ownership, high free cash flow will tend to distribute higher ratio of dividend. The firm size variable (SIZE), which represents total asset of all listed companies in Ho Chi Minh Stock Exchange, has negative relationship with dividend payout ratio based on both the Pooled OLS and the Fixed Effect Model. This result is contrast with paper's hypothesis that firm size is positively related to dividend payout ratio. However this value is statistically significant at 0.05 level. This mean firm size variable has an impact to the dividend policy. This result shows that large-sized firms prefer to pay less dividend; therefore, we fail to reject the null hypothesis that size has negative relationship with dividend payout. Belans (2007), Jeong (2008) and Avazian (2006) come up with contradictory evidence. Large enterprises have easy access to capital markets and mobilize capital with low fees and interests. Because creditors, banks believe the repayment of the companies, they don't necessarily use internal capital

Company profitability (PROF) – ROA , on the one hand is positively associated with dividend payout ratio. This result is consistent with the paper's hypothesis. This shows that firms with high profits used it as signaling device for future performance. A firm's profitability is considered an important factor in influencing dividend payment policy. This result supports the life cycle theory which explains that mature firms with more profit can pay more dividends. Here findings of this study are accepting H1. This result supports the dividend smoothing hypothesis as reported by Nuhu, Musah and Senyo (2014). The profitability has a positive impact on the dividend policy of company listed on the securities market of Vietnam. This may explain that company with good profitability will pay dividends to shareholders. At the same time, the previous dividend policy has a positive impact on the dividend policy of the next period, however, the company size does not affect the dividend policy.

For free cash flow (FCF) , the regression coefficient of this variable is positive under the Pooled OLS and Fixed Effect Model, which is actually consistent with paper's hypothesis. As expected, the results indicate significant positive relationship between free cash flow and dividend payout ratio. The results of this study suggest that firm with good and stable cash flow are able to pay dividend easily compared with firms with

unstable cash flow position. Financial leverage has a negative impact on dividend policy of enterprises listed on the securities market of Vietnam. This can be explained that the higher the debt rate is higher the risk. When the cost of capital is high, the business must pay attention to the debt payment rather than dividends payment.

For insider ownership, the regression coefficient of this variable is negative significant under the Pooled OLS and Fixed Effect Model, which is actually consistent with the paper's hypothesis. Because Viet Nam is the new market, information asymmetry between management (internal) and investors (external) whereby investors have no more information and know less about the company compared to management therefore, they may not appreciate the stock and make excessive sell-offs that reduce the share price.

For financial liquidity and earning per share, the results of this study indicate that financial liquidity has positive impact with dividend payout ratio but insignificant. And earning per share variable which has negative impact and significant relationship with dividend payout ratio. The relationship between the firm's liquidity and dividend payout ratio is positive which explains that firms with more market liquidity pay more dividends. Reddy (2006), Amidu and Abor (2006) find opposite evidence and Belans (2007) have come up with the same conclusion.

From Table 5, the FEM indicates that PROF is significant and positively related to DPR. This is explained in that when ROA increases by 1%, DIV increases by 0.29%. According to the research assumption, firms with high and stable profitability may have a strong cash flow to pay dividends. Therefore, this result is explained by the pecking order theory that firms want to retain more earnings to avoid high costs, and explains the higher the profit of firms, the lower the dividends. The model indicates that LEV has a negative and statistically significant relationship with DIV. When financial leverage increases by 1%, DPR decreases by 0.004%. This result is expected with the research prediction from transaction cost theory. According to this theory, firms with high financial leverage tend to reduce the dividend payments to avoid high transaction costs and the other costs. However, the value of the LEV's beta is quite small, means that the effect on the dividend payout ratio of leverage is not significant as previously expected.

The first econometric model that has been used to deal with the panel data is Pooled Ordinary Least Square (Pooled OLS). This model tests how the independent variables affect the dependent variable with assumptions. Among the 7 explanatory variables, 5 variables have a statistical effect on the dividend payout ratio at the significant at 5% level. In order to choosing the model of this study which consistent with my hypotheses and clear explain about the relationship between seven independent variables and dependent variable dividend payout ratio, this study used Likelihood

ratio and Hausman test. Hausman test shows that there are p-value is approximately 0% smaller than 5% so the Fixed Effect Model is the relevant model. Beside to choosing model between the Ordinary Least Square and Fixed Effect Model, Likelihood ratio is used. Finally, this study chooses the Fixed Effect Model with the largest Likelihood value. The Fixed Effect Model with 7 variables is the chosen model to study (Table 4). The regression with the Fixed Effect Model is illustrated in Table 5. This means the Fixed Effect Model can be chosen as the independent variables and may explain the change of the dependent variable (DIV). To estimate the appropriation of beta coefficients individually, this study continues to compare each P-value with 5%. The null hypothesis is “ $\beta_i = 0$ ” (with $i = [1; 10]$). If the P-value is greater than 5%, the null hypothesis cannot be rejected.

In comparing the results of the Fixed Effect Model and Random Effect Model, this research favors the results of the FE model as the better fitting model because the p-value of Likelihood is $0 < 0.05$. based on the Hausman test result, Random Effect Model is not appropriate. However, as the observation period 5 year is much smaller than the cross section with around 154 sample firms. This is insufficient for applying the Period Fixed Effect. Thus make this study uses the Cross-section Fixed Effect for testing the coefficient between the explanatory variables.

Table 10: Summary of hypothesized and empirical relationship between determinants and dividend payout ratio

Variable	Hypothesized relationship	Result from this study
PROF	+	+
SIZE	+	-
LEV	-	-
CR	+	+
FCF	+	+
INS	-	-
EPS	+	-

In conclusion, the result emphasizes the relevance on dividend payout policy, which importantly contribute to better understand the behavior practice of the listed companies in the Ho Chi Minh stock Exchange. Thus this study is not only provide important policy lesson for the market controllers, the regulation issuers, but also apply a further view for investors in decision making. In sort, dividend policy is the most important with both investor and financial manager, the firms.

5 Conclusion and Limitations

5.1 Discussion

This research examines whether the eight factors determined, namely: profitability, firm size, finance leverage, liquidity, insider ownership, earning per share and free cash flow affect the dividend payout policy of listed companies in Ho Chi Minh Stock Market. Three types of models are Pooled OLS, Fixed Effect Model and Random Effect Model to find out specific relationship and characteristics of each variable with dividend payout policy of the company.

This study has already considered the dividend policy is one of the most debatable topics in corporate finance and it is one of the most important decisions of financial management. Dividend policy provides the information content for investors in the stock market to making investment decisions. Information on the dividend policy of the listed companies show the presence of factors affecting the companies policy to distribute the dividend significantly and insignificantly for the decisions of financial management of the Vietnam security market. The purpose of the research was to find determinant of dividend policy of listed companies in Vietnam stock market. The results of this research will help the investors that their forecasts should be more accurate and making investment decisions. Companies with large investment needs but limited access to capital will give higher priority to retaining reinvestment profits to meet growth needs. Companies that are heavily indebted, high debt ratios often pay low dividends to prioritize debt financing. For most small and medium-sized companies in the Vietnamese economy, accessing capital from banks or issuing shares is not easy, so these companies often have to rely more on Endogenous capital is the retained earnings, so they often pay low dividends or don't pay dividends.

Generally, findings of this study are in-line with previous empirical evidences. Based on the analysis of the factors that affect the companies' dividend policy of the listed companies for the period of 2014 - 2018, it can be concluded that during the period of observation, the variables of debt to equity ratio, return on assets, firm size, financial leverage, free cash flow, inside ownership have significant influence while the variable of current ratio and earning per share has effect but not significant toward dividend payout ratio on the listed companies

Results of this study proved positive significant impact of profitability, return on asset with dividend payout policy. Positive significant impact of return of asset shows that Return on assets (ROA) is an indicator of how profitable a company is relative to its total assets. ROA gives a manager, investor, or analyst an idea as to how efficient a company's management is at using its assets to generate earnings. About firm size factor, it has a negative related with the decision making dividend policy. Negative significant impact of the firm size show that the large size company pay low dividends. In fact, for most small and medium-sized companies in the Vietnamese economy, accessing capital from banks or issuing shares is not easy, so these companies often have to rely more on

Endogenous capital is the retained earnings, so they often pay low dividends or don't pay dividends. And the large listed joint stock companies have better access to capital than small businesses, so they often pursue a policy of dividend stabilization. Dividend stabilization policy is a policy pursued by the majority of listed companies because this policy has the advantage of creating a stable cash flow for shareholders, stabilizing shareholder psychology and helping stock prices of the company are appreciated. About financial leverage, this study proved negative significant of the company leverage with dividend payout policy. Negative significant impact of financial leverage show that the higher the debt rate is higher the risk. When the cost of capital is high, the business must pay attention to the debt payment rather than dividends payment.

Based on the results of this study, the author propose some recommendations: Investors need to study the financial status of the business as the profitability because it will affect to the dividends payment of the next period. High debt ratio will negatively affect dividend payment. The manager should have an analysis of the advantages and disadvantages of each type of dividend policy and consider which one will be suitable with the specific characteristics of company. Most importantly, managers have a clear choice of dividends policy and pursue that choice. Because, in order to maintain dividend payments, it is imperative for managers to have a long-term financial and investment strategy, a more responsible for raising capital efficiency, helping to increase the company value in the long run. Enterprises should prioritize stable dividend policy to maintain a certain level of dividends and increase dividends to a higher level only in the case that the company can achieve a stable increased profitability and have an ability to increase dividend. Once the dividend has been increased, company must try to maintain this dividend level until the company sees that there is no hope to prevent a decline in profitability in the future.

The thesis has analyzed in detail the factors affecting the decision making of dividend policy of companies listed on Ho Chi Minh Stock Exchange. The new factor is insider ownership, is statistically significant. It show that the decision making dividend policy of listed companies is still depend on the number of shareholder in the board of directors. The thesis has built a linear regression model which is the basis for companies to determine dividend payment. At the same time, it is realizes that psychology prefers cash dividends rather than future earnings. It is the risk aversion of investors, especially in the Vietnamese market, which is a very new market.

5.2 Limitation

Although, the study provides a considerable amount of contribution, there still exist some limitations and suggested future studies to be improves in next researches. Author realizes that the study has limitations of data, the data in this research is collected from listed companies in Ho Chi Minh Stock Market in the period from 2014

-2018, five year is the period not enough long time to be finding the change in the Ho Chi Minh stock market, further research can be carried out with the addition of the study period in analyzing the factors that affect the listed companies' dividend policies. Because the Vietnamese stock market has just developed in recent years, that the reason The data used in this study is limited to medium and large company listed on the Ho Chi Minh Stock Exchange, southern of Vietnam, so the results are not yet able to be applied in all companies Vietnam, further research is expected to use more companies or all companies so that the results can be improved and provide better generalization.

5.3 Future research

From the limitation of this research should be applied to resolve the problems. Future studies are suggested to increase the data span and cover all of the Ha Noi stock Exchange not included in this study. Most of Ho Chi Minh stock Exchange listed companies are still not publicly. Future studies can try investigating the factors affecting the decisions making dividend payout policy and can also extend the number of significant determinants. There are some factors have not been put in this model in this study. So in further researches author will use factor to make run dedicate determinant of dividend payout policy. Regardless of these limitations, this paper can be provides a good perspective to the investors and financial management. Paper is also helpful for Vietnamese investor and financial managers who want to study factors affecting the company's dividend payout policy for their further researches and in making investment decision, respectively.
